Critiques

- 1/2 page critiques of research papers
- Due at 10am on the class day (hard deadline)
- Email Yehan yehan.ma@wustl.edu in plain txt
- Back-of-envelop notes - NOT whole essays

Critique #1
- Due on 1/30 (Tuesday)
IoT Operating Systems

Chenyang Lu
TinyOS and nesC

- TinyOS: OS for wireless sensor networks.
- nesC: programming language for TinyOS.
Mica2 Mote

- Microcontroller: 7.4 MHz, 8 bit
- Memory: 4KB data, 128 KB program
- Radio: max 38.4 Kbps
- Sensors: Light, temperature, acceleration, acoustic, magnetic…
- Power
  - <1 week on two AA batteries in active mode
  - >1 year battery life on sleep modes!

- Contrast to Raspberry Pi:
Epic Core

- I/O (some shared)
- 8 ADC (12 bit)
- 2 DAC (12 bit)
- 1 I2C
- 1 JTAG
- 1 1-Wire
- 2 SPI
- 2 UART
- 8 general, 8 interrupt, and 5 special pin connectors

- CC2420 radio
  - 802.15.4
  - 6LoWPAN/IPv6
- TI MSP430
- Clock 4/8 MHz

- RAM 10 KB
- Flash 48 KB

- 16 MB Flash memory

- Unique hardware ID

- 3 V

Typical sleep current 9μA at 3V, radio active ~20mA
TelosB

- Six major I/O devices
- Possible Concurrency
  - I²C, SPI, ADC
- Energy Management
  - Turn peripherals on only when needed
  - Turn off otherwise

Diagram:

- Humidity
- Temp
- I²C
- MSP430
- SPI
- ADC
- Radio
- Flash
- Total Solar
- Photo Active
Hardware Constraints

Severe constraints on power, size, and cost →

- slow microprocessor
- low-bandwidth radio
- limited memory
- limited hardware parallelism → CPU hit by many interrupts!
- manage sleep modes in hardware components
Software Challenges

- **Small** memory footprint
- **Efficiency** - power and processing
- **Concurrency-intensive** operations
- Diversity in applications & platform → **efficient modularity**
  - Support reconfigurable hardware and software
Traditional OS

- Multi-threaded
- Preemptive scheduling
- Threads:
  - ready to run;
  - executing on the CPU;
  - waiting for data.
Limitations of Traditional OS

- Multi-threaded + preemptive scheduling
  - Preempted threads waste memory
  - Context switch overhead

- I/O
  - Blocking I/O: waste memory on blocked threads
  - Polling (busy-wait): waste CPU cycles and power
Example: Preemptive Priority Scheduling

- Each process has a fixed priority (1 highest);
- \( P_1 \): priority 1; \( P_2 \): priority 2; \( P_3 \): priority 3.

![Diagram showing the scheduling of processes]

- \( P_2 \) released
- \( P_3 \) released
- \( P_1 \) released

Time line:
- 0 10 20 30 40 50 60
- Process: \( P_2 \) - \( P_1 \) - \( P_2 \) - \( P_3 \)
Context Switch

- process 1
- process 2
- ...
## Existing Embedded OS

<table>
<thead>

- QNX context switch = 2400 cycles on x86
- pOSEK context switch > 40 µs
- Creem -> no preemption

Efficient modularity
- Application = scheduler + graph of components
- Compiled into one executable
- Only needed components are compiled/loaded

Concurrency: event-driven architecture

Modified from D. Culler et al., TinyOS boot camp presentation, Feb 2001
Example: Surge

Chenyang Lu
Two-level Scheduling

- Events handle interrupts
  - Interrupts trigger lowest level events
  - Events can signal events, call commands, or post tasks
- Tasks perform deferred computations
- Interrupts preempt tasks and interrupts
Multiple Data Flows

- **Respond quickly**: sequence of event/command through the component graph.
  - Immediate execution of function calls
  - e.g., get bit out of radio before it gets lost.

- Post tasks for deferred computations.
  - e.g., encoding.

- Events preempt tasks to handle new interrupts.
Sending a Message

Timing diagram of event propagation
(step 0-6 takes about 95 microseconds total)
Scheduling

- Interrupts preempt tasks
  - Respond quickly
  - Event/command implemented as function calls

- Task cannot preempt tasks
  - Reduce context switch $\rightarrow$ efficiency
  - Single stack $\rightarrow$ low memory footprint
  - TinyOS 2 supports pluggable task scheduler (default: FIFO).

- Scheduler puts processor to sleep when
  - no event/command is running
  - task queue is empty
Space Breakdown...

Code size for ad hoc networking application

- **Interrupts**: 144 Bytes code
- **Message Dispatch**: 331 Bytes code
- **Initialization**: 470 Bytes code
- **C-Runtime**: 283 Bytes code
- **Light Sensor**: 128 Bytes code
- **Clock**: 251 Bytes code
- **Scheduler**: 144 Bytes code
- **Led Control**: 219 Bytes code
- **Messaging Layer**: 192 Bytes code
- **Packet Layer**: 77 Bytes code
- **Radio Interface**: 219 Bytes code
- **Routing Application**: 226 Bytes code
- **Radio Byte Encoder**: 188 Bytes code

**Totals:**
- 3430 Bytes code
- 226 Bytes data

D. Culler et. Al., TinyOS boot camp presentation, Feb 2001
Lithium Battery runs for 35 hours at peak load and years at minimum load!

- That’s three orders of magnitude difference!

A one byte transmission uses the same energy as approx 11000 cycles of computation.
### Components

</tbody>
</table>

- 50 cycle task overhead (6 byte copies)
- 10 cycle event overhead (1.25 byte copies)
Advantages

- Small memory footprint
  - Only needed components are compiled/loaded
  - Single stack for tasks

- Power efficiency
  - Put CPU to sleep whenever the task queue is empty
  - TinyOS 2 (ICEM) provides power management for peripherals.

- Efficient modularity
  - Event/command interfaces between components
  - Event/command implemented as function calls

- Concurrency-intensive operations
  - Event/command + tasks
Critiques

- No protection barrier between kernel and applications
- No preemptive scheduling → a real-time task may wait for non-urgent ones
- Static linking → cannot change parts of the code dynamically
- Virtual memory?
nesC

- Programming language for TinyOS and applications

- Support TinyOS components

- Whole-program analysis at compile time
  - Improve robustness: detect race conditions
  - Optimization: function inlining

- Static language
  - No function pointer
  - No malloc
  - Call graph and variable access are known at compile time
Application

- **Interfaces**
  - provides interface
  - uses interface

- **Implementation**
  - module: C behavior
  - configuration: select & wire

```c
module TimerP {
    provides {
        interface StdControl;
        interface Timer;
    }
    uses interface Clock;
    ...
}
```
interface Clock {
    command error_t setRate(char interval, char scale);
    event error_t fire();
}

interface Send {
    command error_t send(message_t *msg, uint16_t length);
    event error_t sendDone(message_t *msg, error_t success);
}

interface ADC {
    command error_t getData();
    event error_t dataReady(uint16_t data);
}

Bidirectional interface supports split-phase operation
module SurgeP {
    provides interface StdControl;
    uses interface ADC;
    uses interface Timer;
    uses interface Send;
}

implementation {
    bool busy;
    norace uint16_t sensorReading;
    async event result_t Timer.fired() {
        bool localBusy;
        atomic {
            localBusy = busy;
            busy = TRUE;
        }
        if (!localBusy)
            call ADC.getData();
        return SUCCESS;
    }
    async event result_t ADC.dataReady(uint16_t data) {
        sensorReading = data;
        post sendData();
        return SUCCESS;
    }
    ...
}
configuration TimerC {
  provides {
    interface StdControl;
    interface Timer;
  }
}

implementation {
  components TimerP, HWClock;

  StdControl = TimerP.StdControl;
  Timer = TimerP.Timer;

  TimerP.Clock -> HWClock.Clock;
}
Example: Surge
Concurrency

- Race condition: concurrent interrupts/tasks update shared variables.

- Asynchronous code (AC): reachable from at least one interrupt.
- Synchronous code (SC): reachable from tasks only.

- Any update of a shared variable from AC is a potential race condition!
module SurgeP { ... }

implementation {
    bool busy;
    norace uint16_t sensorReading;

    async event result_t Timer.fired() {
        if (!busy) {
            busy = TRUE;
            call ADC.getData();
        }
        return SUCCESS;
    }

    task void sendData() { // send sensorReading
        adcPacket.data = sensorReading;
        call Send.send(&adcPacket, sizeof adcPacket.data);
        return SUCCESS;
    }

    async event result_t ADC.dataReady(uint16_t data) {
        sensorReading = data;
        post sendData();
        return SUCCESS;
    }
}
Atomic Sections

```c
atomic {
    <Statement list>
}
```

- **Disable interrupt** when atomic code is being executed
- **But cannot disable interrupt for long!**
  - No loop
  - No command/event
  - Function calls OK, but callee must meet restrictions too
module SurgeP { ... }

implementation {
    bool busy;
    norace uint16_t sensorReading;

    async event result_t Timer.fired() {
        bool localBusy;
        atomic {
            localBusy = busy;
            busy = TRUE;
        }  
        if (!localBusy)
            call ADC.getData();
        return SUCCESS;
    }
}
Race-free invariant: any update of a shared variable
  - is from SC only, or
  - occurs within an atomic section.

Compiler returns error if the invariant is violated.

Fix
  - Make access to shared variables atomic.
  - Move access to shared variables to tasks.
Results

- Tested on full TinyOS code, plus applications
  - 186 modules (121 modules, 65 configurations)
  - 20-69 modules/app, 35 average
  - 17 tasks, 75 events on average (per application) - lots of concurrency!

- Found 156 races: 103 real
  - About 6 per 1000 lines of code!

- Fixed races:
  - Add atomic sections
  - Post tasks (move code to task context)
Optimization: Inlining

- Inlining improves performance and reduces code size.
- Why?

Overhead for Function Calls

- **Caller: call a function**
  - Push return address to stack
  - Push parameters to stack
  - Jump to function

- **Callee: receive a call**
  - Pop parameters from stack

- **Callee: return**
  - Pop return address from stack
  - Push return value to stack
  - Jump back to caller

- **Caller: return**
  - Pop return value

*Many overhead instructions for function calls!*
Principles Revisited

- **Support TinyOS components**
  - Interface, modules, configuration

- **Whole-program analysis and optimization**
  - Improve robustness: detect race conditions
  - Optimization: function inlining
  - More: memory footprint.

- **Static language**
  - No malloc, no function pointers
Critiques

- No dynamic memory allocation
  - Bound memory footprint
  - Allow offline footprint analysis
  - How to size buffer when data size varies dynamically?

- Restriction: no “long-running” code in
  - command/event handlers
  - atomic sections
Commercial IoT OS

- **Contiki**: open-source, multi-threaded OS, plain C.

- **Amazon FreeRTOS**: open-source FreeRTOS kernel + libraries to securely connect devices to AWS cloud services.

- **Arm Mbed**: open-source OS based on an Arm Cortex-M microcontroller.

- **Android Things**: SDK similar to traditional Android mobile development and involves writing apps using the Android framework and tools.

- **Windows 10 IoT Core**: a version of Windows 10 that is optimized for smaller devices and that runs on both ARM and x86/x64 devices.
