Low Power WAN Protocols for IoT: IEEE 802.11ah, LoRaWAN

Raj Jain
Washington University in Saint Louis
Saint Louis, MO 63130
Jain@cse.wustl.edu

Audio/Video recordings of this class lecture are available at:
http://www.cse.wustl.edu/~jain/cse574-16/

Overview

1. Low Power WANs
2. IEEE 802.11ah
3. LoRaWAN

Note: This is the 5th lecture in series of class lectures on IoT. Bluetooth, Bluetooth Smart, IEEE 802.15.4, ZigBee were covered in the previous lectures.

Recent Protocols for IoT

MQTT, SMQTT, CoRE, DDS, AMQP, XMPP, CoAP, IEC,…

Security

IEEE 1888.3, TCG, Oath 2.0, SMACK, SASL, EDSA, ace, DTLS, Dice,…

Encapsulation

IEEE 1888.3, TCG, Oath 2.0, SMACK, SASL, EDSA, ace, DTLS, Dice,…

LowPAN, 6TiSCH, 6Lo, Thread…

Routing

RPL, CORPL, CARP

Network

CoAP, IEC, …

Session

MQTT, SMQTT, CoRE, DDS, AMQP, XMPP, CoAP, IEC,…

RPL, CORPL, CARP

WiFi, 802.11ah, Bluetooth Low Energy, Z-Wave, ZigBee Smart, DECT/ULE, 3G/LTE, NFC, Weightless, HomePlug GP, 802.15.4e, G.9959, WirelessHART, DASH7, ANT+, LTE-A, LoRaWAN, ISA100.11a, DigiMesh, WiMAX, …

Datalink

802.11ah Features

- Aka “WiFi HaLow” by WiFi Alliance.
- IEEE spec for Low-rate long-range IoT applications. Currently in 2nd Sponsor ballot (March 2016).
- Spectrum: Sub-Giga Hertz license-exempt spectrum. Not including TV white spaces (700 MHz for 802.11af).
  - 902-928 MHz (USA)
  - 863-868.6 MHz (Europe)
  - 916.5-927.5 MHz (Japan)
  - 755-587 MHz (China)
  - 917.5-923.5 MHz (Korea)
- Sub-GHz frequency: Longer range than 2.4 GHz, less congested, better penetration
- Low bit rate for IoT, Short data transmissions, Power savings, Efficient MAC
- Goal: Support at least 4x devices per AP than legacy 802.11
802.11 Standards: Ranges

- 150 kbps to 78 Mbps per spatial stream (up to 4 streams)

802.11 Standards: Ranges

802.11ah

60 GHz

802.11a/n/ac

802.11b/g/n

802.11af

802.11ah PHY

1. 802.11ac PHY down clobbered by 10X
   - 2/4/8/16 MHz channels in place of 20/40/80/160 MHz in ac
   - 20 MHz 11ac and 2 MHz 11ah both have 64 FFT size and 48 data subcarriers + 4 pilots \(\Rightarrow 1/10^th\) inter-carrier spacing
     \(\Rightarrow 10X\) longer Symbols \(\Rightarrow\) Allows 10X delay spread
     \(\Rightarrow\) All times (SIFS, A CKs) are 10x longer
   - New 1 MHz PHY with 32 FFT and 24 data subcarriers
2. Adjacent channel bonding: 1MHz+1MHz = 2 MHz
3. All stations have to support 1MHz and 2MHz
4. Up to 4 spatial streams (compared to 8 in 11ac)
5. 1 MHz also allows a new MCS 10 which is MCS0 with 2x repetition \(\Rightarrow\) Allows 9 times longer reach than 2.4GHz
6. Beam forming to create sectors

802.11 MAC

- Large number of devices per Access Point (AP)
  - Hierarchical Association Identifier (AID)
- Relays are used to allow connectivity outside the coverage area. Limited to 2-hops.
- Power Savings Enhancements:
  - Allows stations to sleep and save energy.
  - AP negotiates a Target Wake Time (TWT) for individual stations
- Speed frame exchange allows stations to exchange a sequence of frames for a TXOP.

©2016 Raj Jain

Washington University in St. Louis http://www.ee.wustl.edu/~jain/cse574-16
MAC Protocol Versions

- Protocol Version 0 (PV0) is same as that for b/a/g/n/ac
- Protocol version 1 (PV1) is optimized for IoT
  - Short headers
  - Null Data packets
  - Speed packet exchange
  - Improved channel access

Short MAC Header

- MAC Header shortened by 12-26 Bytes:
  - Removed: High throughput control, QoS, Duration field (No virtual carrier sensing)
  - Optional: 3rd address
  - 2-byte AID in place of some 6-byte addresses
  - Frame Control indicates what protocol version is being used
  - Sequence field indicates if 3rd/4th addresses are present

Null Data Packet (NDP)

- Removed: MAC header, Frame check sequence and preamble from the ACK frame ⇒ Only PHY bits.
- ACK frame identified by Modulation (MCS) type
- Block ACK is also NDP with another MCS
- Clear to Send (CTS) is another NDP with a new MCS

Speed Frame Exchange

- Also called “Bi Directional Transmit (BDT)”
- Initiator sends a frame with response indicator set to “long response”
  - Receiver can send data instead of ACK within a SIFS
  - Frames are sent until there are no more frames
Types of Stations

- **High-Traffic**: Listens to Traffic Indication Map (TIM) in beacons and transmit accordingly within a restricted access window ⇒ *TIM Stations*
- **Periodic Low-Traffic**: Negotiate a transmission time allocated in a periodic restricted access windows. Do not listen to beacons ⇒ *Non-TIM Stations*
- **Very Low-Traffic**: Send a poll to AP and get a transmission opportunity in response ⇒ *Unscheduled Stations*

Channel Access for TIM

- Each station knows what segments they belong to.
- Stations wake up every “DTIM” interval and find out which beacon they should listen to. The beacon has detailed map indicating which station has pending traffic and when stations can contend for access.
- If the map indicates, AP has buffered packets for a station, the station uses DCF (distributed coordination function) to send a PS-poll to get the packet.
- If a station has a packet to send, it listens to the map and uses DCF to send RTS.
- Small number of stations per slot reduces chances of collisions.
- Under low load, it becomes TDMA.

Response Indication Deferral (RID)

- New virtual carrier sense mechanism replacing NAV (Network Allocation Vector).
- Can not use NAV since there is no duration field.
- RID is also a time count down mechanism similar to NAV.
- RID is set after reception of PHY header.
- NAV is set after reception of complete frame.
- RID is set based on the 2-bit response indication field in the PHY header.
  - Normal Response: RID ← SIFS + Ack or Block Ack time
  - NDP Response: RID ← SIFS + NDP Frame time
  - No Response (Broadcast frames): RID ← 0
  - Long Response: RID ← SIFS + Longest transmission time (Used with Speed Frame Exchange)

Power Enhancements

- Page Segmentation
- Restricted Access Window
- Target Wake Time
Page Segmentation

- Announcing all buffered frames in each beacon ⇒ 8096 bits would be wasted per beacon interval
- AP segments the TIM stations in segments and announces only one segment at a time.
- Every Delivery TIM (DTIM) interval, AP announces which segments have pending data and downlink, uplink periods.

Association Identifier

- 802.11 b/g/n/ac use 11-bit identifier ⇒ 2007 stations
  - 2000+ bits required in “Traffic Indication Map (TIM)”
- 802.11ah uses 16-bit identifier ⇒ 8X stations
  - 8 pages of ~$2^{11}$ stations each. Actually 2007 stations. Currently only page 0 is allowed. Page 1-7 are reserved. First 2 bits should be 11 to distinguish AID from duration and others.

</tr>
</tbody>
</table>

Restricted Access Window (RAW)

- Allows a set of slot to be restricted to a group of stations ⇒ Reduces contention
- A TIM station can be allocated slots during restricted access window (RAW) to transmit/receive packets
- RAW is a part of “Contention Free Period”
- Access may granted for transmission, reception, polling, etc for one or a group of stations
- A raw schedule is transmitted at the beginning of raw interval
- A station can tell AP that it has a frame to transmit using a Uplink Data Indication (UDI) bit
- Dividing stations into groups and dividing time into slots for each group increases the efficiency under heavy load.
  - At 100% load: RAW gives close to 100%.
    Regular EDCF gives 0%.

Other RAWs

- **Periodic RAW**: Period and duration of PRAW are announced by AP
- **Sounding RAW**: used for sector sounding
- **AP Power Management RAW**: use by AP to announce the time when it will be sleeping
- **Non-TIM RAW**: Protects transmission of non-TIM stations
- **Triggering Frame RAW**: Used to allow stations to send PS-poll frames indicating their need to transmit
Target Wake Time (TWT)

- Association request and responses include Target-Wake-Time, Minimum-Wake-Duration, and Wake Interval mantissa.
- AP sends a “Null Data Packet (NDP)” to a station at its target wake up time containing buffering status. A station can then send a PS-poll and get its frames.
- Target Wake Time can be very large

![Diagram showing active and sleep states for stations 802.11ah STA1 and STA2 and AP 802.11ah]

Authentication

- New mechanisms to allow authentication of a large number of stations
  - **Centralized Authentication:**
    - AP announces a threshold in the beacon.
    - Each station draws a random number between 0 and 1022.
    - Station attempts authentication only if # is less than the threshold.
  - **Distributed Authentication:**
    - Truncated Binary Exponential Backoff
    - Each station draws a random slot #
    - Extends the range if unsuccessful

Group Sectorization

- AP can divide the space in sectors
  - Each station is told which sector it belongs to.
- Beacon announces which sectors can transmit in this sector interval
- Some sector intervals may be for omni-directional transmissions
  - Some may be for only some sectors
- Allows spatial reuse and increase throughput

![Diagram illustrating sectorization]

802.11ah: Summary

1. 802.11ah runs at 900 MHz band ⇒ Longer distance
2. 802.11ah is 802.11ac down by 10x.
   - It uses OFDM with 1/2/4/8/16 MHz channels.
   - Longer symbols ⇒ Longer multi-path
3. MAC is more efficient by eliminating reducing header, aggregating acks, null data packets, speed frame exchanges
4. Saves energy by allowing stations and AP to sleep longer using Target Wakeup Time, Restricted Access Window
Other LPWANs

Low Power Wide Area Networks (LPWANs)

- **LoRaWAN**, [https://www.lora-alliance.org](https://www.lora-alliance.org)
- Weightless-P (High Performance), [http://www.weightless.org/](http://www.weightless.org/)
- M2M Spectrum, [http://m2mspectrum.com](http://m2mspectrum.com)

LoRaWAN

- Long Range Wide Area Network.
- Originally developed by Cyclos in France. Acquired by Semtech corporation, which formed **LoRa Alliance**. Now 160+ members.
- Rapid Adoption: Products already available on Amazon.

Transceiver  
Arduino  
Radio Shield  
Connectivity Kit for Arduino, Wasp mote, Raspberry Pi

Key Features

- **Bidirectional** communication  
  ⇒ Allows firmware/software updates of end devices
- **Low Rate**: 0.3 kbps to 22 kbps in Europe, 0.9 kbps in US
- **Star of Stars Topology**: Gateways are transparent bridges. Server is the brain. Simple devices. Relays are optional.
- **Secure**: EUI128 Device Key, EUI64 Network Key, EUI64 Application Key

Classes of Devices

- **Class A**: Uplink transmission followed by 2 short downlink Schedule determined by the end point ⇒ Simple devices.  
  - Pure Aloha ⇒ 18.4% =1/2e efficiency under heavy load.
  - Gateways listen to multiple transmissions on multiple channels
  - All gateways listen to all transmissions ⇒ Antenna Diversity.
  - Server selects one gateway for downlink/ack to device ⇒ Mobility
- **Class B**: Class A + extra receive window at scheduled time following the beacon from Gateway  
  - All gateways transmit beacons every 2^t seconds (t=0 to 7)
  - All gateways are synchronized using GPS
  - Device is told receive slot
- **Class C**: Can receive anytime (unless transmitting). Generally on AC power
Frequency

- Uses ISM license-exempt band:
  - 915 MHz in US. Power limit. No duty cycle limit.
  - 868 MHz in Europe. 1% and 10% duty cycle limit
  - 433 MHz in Asia
- Same techniques can be used in 2.4GHz or 5.8 GHz
- Currently suitable for public (single) deployment in an area
  - All gateways report to the same server
  - A device can talk to any gateway
  - All devices use the same frequency

Sources:
- http://www.link-labs.com/what-is-lora/

Chirp Spread Spectrum

- **Chirp**: A signal with continuously increasing (or decreasing) frequency (Whale sound)
- **Chirp Spread Spectrum**:
  - signal is frequency modulated with frequency increasing (or decreasing) from min to max (or max to min) ⇒ power is spread over the entire spectrum

LoRa Modulation

- Designed to achieve high sensitivity using a cheap crystal
- Allows low power transmissions over long distances
- A form of Chirp spread spectrum.
- Data is encoded using the frequency increase/decrease rate
  - Data rate and link condition determines the frequency bandwidth required
- Multiple parallel transmissions with different data rates on the same frequency
- Can receive signals **19.5 dB below** noise floor with forward error correction (FEC)
- Power level is determined adaptively based on data rate and link condition. Fast communication is used to save battery.

Sources:
- “LoRa Physical Layer and RF Interface,” Radio-Electronics,
- Z. Ianelli, “Introduction to Chirp Spread Spectrum (CSS) Technology,” IEEE 802 Tutorial,

LoRaWAN MAC

- LoRaWAN: MAC function over LoRa PHY
- Server manages the network and runs MAC
  - Assigns each device a frequency, spreading code, data rate
  - Eliminates duplicate receptions
  - Schedules acknowledgements
  - Adapts data rates
- All gateways of a network are synchronized
- Data rate is determined by distance and message duration
- Server determines the data rate using an adaptive data rate (ADR) scheme

Sources:
LoRaWAN: Summary

1. LoRaWAN is the new MAC standardized by LoRa Alliance
2. LoRa modulation is a variation of chirp spread spectrum where the rate of frequency increase/decrease is modulated by symbol
   - Increases its resistance to noise
   - Allows multiple parallel transmissions in one frequency
3. Centralized management and media access control using a “server”
4. Devices broadcast to all gateways. The best gateway replies back.

Summary

1. Dozens of protocols for low-power WAN
2. LoRaWAN has already been implemented and is a leading candidate
3. IEEE 802.11ah is a new standard. To be productized.

Lab 1

A. Download InSSIDer v3.1.2.1 from:
   - Measure the signal levels of various WiFi networks
   - Submit a screen capture

B. Download Wireshark from:
   - https://www.wireshark.org/#download
   - Run a trace packets on your wireless network
   - Submit a screen capture
